### Introduction

For our final lab, we will be looking at the SuperLearner library, as well as the Targeted Maximum Likelihood Estimation (TMLE) framework, with an extension to longitudinal data structures. This lab brings together a lot of what we learned about both machine learning and causal inference this year, and serves as an introduction to this intersection S://tutorcs.com

#### Data

For this lab, we will use the Boston dataset from the MASS library. This dataset is a frequently used toy dataset for machine learning. The main variables we are going to predict is medv which is the median home value for a house in Boston.

```
# Load Boston dataset from MASS package
data(Boston, package = "MASS")
glimpse(Boston)

```

## SuperLearner

First, we are going to the first, we are going t

The basic idea underlying SuperLearner is that it combines cross-validation with ensemble learning to create a "meta-estimator" that is a weighted combination of constituent algorithms. This idea should sound familiar from when we explored ensemble methods in sklearning Python.

Train/Test Split

# Assignment Project Exam Help ical train/est split. There are several options for doing this, but we will use the

Let's start with our typical train/test split. There are several options for doing this, but we will use the tidymodels method. Let's take a look:

```
# initial_split function from tidymodels/rsample
boston_split <- inital markstortutores @ 163.com
# Declare the training set with rsample::training()
train <- training(boston_split)</pre>
# y_train is medv where
                       me
y_train <- train %>%
  mutate(medv = ifelse(medv > 22,
                  https://tutorcs.com
  pull(medv)
# x_train is everything but the outcome
x_train <- train %>%
  select(-medv)
# Do the same procedure with the test set
test <- testing(boston_split)</pre>
y_test <- test %>%
  mutate(medv = ifelse(medv > 22,
                    0)) %>%
  pull(medv)
x_test <- test %>%
  select(-medv)
```

SuperLearner Models

Now that we have our train and test partitions set up, let's see what machine learning models we available to us. We can use the listWrappers() function from SuperLearner:

```
listWrappers()
##
    [1] "SL.bartMa
                                                        "SL.biglasso"
##
    [4] "SL.caret'
                                                        "SL.cforest"
    [7] "SL.earth"

##
   [37] "SL.step.interaction"
                                "SL.stepAIC"
                                                        "SL.svm"
## [40] "SL.template"
                                "SL.xgboost"
## [1] "All"
## [1] "screen.corP"
  [4] "screen.randomForest"
                                                           "screen.template"
## [7] "screen.ttest"
                                 "write.screen.template"
```

Notice how we have both prediction a gorithm for operwise training and screening a gorithms for feature selection (some may be both).

Let's go ahead and fit a model. We'll start with a LASSO which we can call via glmnet:

```
##
## Call:
## SuperLearner(Y = y_train, X = x_train, family = binomial(), SL.library = "SL.glmnet")
##
##
##
##

Risk Coef
## SL.glmnet_All 0.09257247 1
```

Notice how it spits out a "Risk" and a "Coef". The "Coef" here is 1 because this is the only model in our ensemble right now. Risk is essentially a measure of accuracy, in this case something like mean squared error. We can see the model in our ensemble that had the lowest risk like this:

```
# Here is the risk of the best model (discrete SuperLearner winner).
# Use which.min boolean to find minimum cvRisk in list
sl_lasso$cvRisk[which.min(sl_lasso$cvRisk)]
```

```
## SL.glmnet_All
## 0.09257247
```

Multiple Models

Now let's extend this framework to multiple models. Within SuperLearner, all we need to do is add models to the SL.library argument:

Now let's move to our validation step. We'll use the predict() function to take our SuperLearner model (only keeping models that had weights) and generate predictions. We can then compare our predictions against our true observations at tutorcs@163.com

```
## # A tibble: 6 x 2
##
       obs pred
##
     <dbl> <dbl>
## 1
         1
                1
## 2
          1
                1
## 3
         1
                1
         0
                0
## 4
## 5
          0
                0
## 6
                0
```

Notice that the predictions are not binary 1/0s, but rather probabilities. So, we recode these so that if estimate >= .5 it becomes a 1, and 0 otherwise. We can then use our standard classification metrics and

create a confusion matrix using caret: True Negatives, predicted a 0 and observed a 0 FN: False Negatives, predicted a 0 and observed a 1 caret::confusionMatrix(as.factor(validation\$pred), Confusion Matrix ## ## Referer 0 Prediction 0 64 11 ## ## 7 45 ## ## 95% CI : (0.7853, 0.9138) ## ## No Information Rate : 0.5591 cstutorcs ## P-Value [Acc ## ## Kappa: 0.7103 ## Assignment Project Exam Help ## Mcnemar's Test P ## Sensitivity: 0.9014 ## Specificity: 0.8036 ## Pos Pred Value at 1533 tutores @ 163.com ## ## Prevalence: 0.5591 ## Detection Rate: 0.5039 ## Detection Prevalence: 0.500 ## Balanced Actuacy: 0.85249389476 ## ## 'Positive' Class : 0 ## ## https://tutorcs.com

#### Ensemble Learning and Parallel Processing

SuperLearner can take a long time to run, but we can also speed this up with parallelization. Unfortunately this works slightly differently in Windows and Mac/Linux (R doesn't seem to recognize Windows Subsystem for Linux).

#### Targeted Maximum Likelihood Estimation (TMLE)

We're now ready to move to the TMLE framework. TMLE combines machine learning and causal inference by using machine learning (i.e. data-adaptive models) to estimate some quantity of interest (so making inference). The key is that even though machine learning models oftentimes do not have outputs like coefficients, they can still be used to target the estimator (i.e. a regression) to that quantity of interest. This has a few different benefits, the primary one being that this framework creates a **doubly robust** estimator. Double robustness means that if we either:

- 1. Fit the right model to estimate the expected outcome correctly
- 2. Fit the model to estimate the probability of treatment correctly

OR

Then the final TMLE estimator will be **consistent**. Consistent means that as the sample size grows to infinity, the bias will drop to 0. We're soing to explore the idea in Cept). The warping we sell go through here is drawn from Katherine Holman's blog. She also provides visual guides to superhearner and TMLE. I recommend consulting the TMLE visual guide in particular as you work through these steps.

The basic procedure we have the solution of t

Step 1: Initial Estimate of the Outcome

The first step in TMLE is to estimate the **outcome model**, or the prediction of our target, Y, conditional on the treatment status, A and covariates features, W SVelocid is this via a classic regression model, but we could also flexibly fit the model using machine learning. In this case, we'll create a SuperLearner ensemble. This Q step gives us our initial estimate. Do the following:

- 3. Fit the SuperLearner model for the Q step to obtain an initial estimate of the outcome

```
# SuperLearner libraries
sl_libs <- c('SL.glmret'
                             1. tutorcs@163.com
# Prepare data for SuperLearner/TMLE
# Mutate Y, A for outcome and treatment, use tax, age, and crim as covariates
data obs <- Boston %>%
 mutate(Y = ifelse(neg))
                      0)) %>%
 rename(A = chas) %>%
 select(Y, A, tax, https://tutorcs.com
# Data Prep
# Outcome
Y <- data_obs %>% pull(Y)
# Covariates
W_A <- data_obs %>% select(-Y)
# Fit SL for Q step, initial estimate of the outcome
Q \leftarrow SuperLearner(Y = Y,
                 X = W A
                 family = binomial(),
                 SL.library = sl_libs)
```

Now that we have trained our model, we need to create predictions for three different scenarios:

- 1. Predictions assuming every unit had its observed treatment status.
- 2. Predictions assuming every unit was treated.
- 3. Predictions assuming every unit was control.

Fill in the code to obtain these predictions.

```
# observed treatment
Q_A <- as.vector(pre軽(原代写代做 CS编程辅导
# if every unit was treated
W A1 <- W A %>% mutate(
Q_1 <- as.vector(pre
                                   _A1) $pred)
# if everyone was
W AO <- W A %>% muta
Q_0 <- as.vector(pre
                                   A0)$pred)
We can take our predic
                                   nto one dataframe:
dat_tmle <- tibble()</pre>
                                     Q_0, Q_1
head(dat_tmle)
## # A tibble: 6 x 5
                             at: cstutorcs
##
             Α
##
    <dbl> <int> <dbl>
             0 0.802 0.802 0.849
## 1
        1
             0 0.236 0.236 0.315
## 2
             o o.674 Stigment Project Exam Help
## 3
             0 0.889 0.889 0.916
## 5
             0 0.847 0.847 0.876
```

We could go ahead and grabon ATT how using Computation which is the difference in expected outcomes under treatment and control conditional on covariates. However, the estimate we get below is targeted (optimized the bias-variance tradeoff) at the predictions of the outcome, not the ATE.

## Step 2: Probability to Steme Lutores.com

Now that we have an initial estimate, we want to "target" it. To do this, we first need to estimate the probability of every unit receiving treatment. This step should look similar to how we estimated the propensity score during matching. Fit a g model using SuperLearner. **Hint**: Think carefully about what should be supplied to the Y and X arguments here.

Now that we have a model for our propensity score, we can go ahead and calculate both the inverse probability of receiving treatment and the negative inverse probability of not receiving treatment (basically the probability of not receiving treatment). Fill in the code below to obtain both of these quantities. **Hint**: The name "negative inverse probability of not receiving treatment" is a mouthful but should give you a hint about how to set up the calculation.

# # Prediction for probability of treats to the CS编程辅导 g\_w <- as.vector(predict)

# probability of treatment

 $H_1 \leftarrow 1/g_w$ 

# probability of co  $H_0 \leftarrow -1/(1-g_w)$ 

We can then create the the probability of contr

assigns the probability of treatment to treated variables, and

```
to dat_tmle
dat_tmle <- # add c</pre>
  dat_tmle %>%
  bind_cols(
         H_1 = H_1,
 mutate(H_A = case_when(A == 1 ~ H_1; CStutorcs
                       A == 0 \sim H O))
```

We now have the initial eximate of the outcome  $Q_{A}$  and the estimates for the probability of Irelandian  $H_A$ .

#### Step 3: Fluctuation Parameter

We are now ready to update principal estimate, 24 yrantice (160 m tion from our prensity score estimates,  $H_A$ . We perform this update by litting a logistic regression where we predict our outcome after passing our initial estiamte,  $Q_A$  through a logistic transformation and then fitting a logistic regression (the -1 + offset() here is necessary because our intercept term is not constant).

```
glm_fit <- glm(Y ~</pre>
                                                  LA, daa=dat_tmle, family=binomial)
```

We can then grab the coefficient from our model:

```
eps <- coef(glm_fit)
```

eps (or epsilon/ $\hat{\epsilon}$ ) is the fluctuation parameter. This is the coefficient on our "clever covariate", and basically tells us how much to update our intial model, Q by.

#### Step 4: Update Initial Estimates

We can now update the expected outcome for all of observations, conditional on their observed treatment status and their covariates:

```
H A <- dat tmle$H A
Q_A_update <- plogis(qlogis(Q_A) + eps*H_A)
```

Do the same for outcome under treatment:

```
Q_1_update <- plogis(qlogis(Q_1) + eps*H_1)
```

Do the same for outcome under control:

```
Q_0_update <- plogis(qlogis(Q_0) + eps*H_0)
```

We now have updated expected outcomes for each unit for their actual treatment status, as well as simulated if they were all in treatment and all in control.

```
Step 5: Compute the Statistical Estimand of Interest
Fill in the code to calculate the ATE using our updated information for
tmle_ate <- mean(Q_1_update - Q_0_update)</pre>
tmle_ate
## [1] 0.2051534
Step 6: Calculate
                                        for CIs and p-values
And finally calculate the
                                         values:
infl fn <- (Y - Q A
                                      \blacksquare_update - Q_0_update - tmle_ate
tmle_se <- sqrt(var(infl_fn)/nrow(data_obs))</pre>
conf_low <- tmle_ate - 1.26 tml = sq +
conf_high <- tmle_ate + 1.96*tml
pval <- 2 * (1 - pnorm(abs(tmle_ate / tmle_se)))</pre>
Via TMLE Package Ssignment Project Exam Help
Thankfully, we do not need to take all of these steps every time we use the TMLE framework. The tmle()
function handles all of this for usl Notice how we get a similar ATT from unning this function: tmle fit <-
tmle fit <-
  tmle::tmle(Y = Y,
           A = A,
           W = W
                           ): 117s49389476
           g.SL.library = sl libs)

#### LTMLE

One of the main shortcomings of the TMLE framework is that it can only handle baseline covariates (covariates measured before treatment). It also requires that intervention happens at a single time point. The ltmle library allows us to relax some of these restrictions so that we can handle time-dependent confounders. The basic setup for the LTI eneed of set up our W, A, and Y, and then pass it to the ltmle() function:

#### Single Time Point

Imagine if there was a tive ordering to an data in contribution a recel like:

$$W1->W2->W3->A->Y$$

Let's simulate some data that Spines this relationship. Notice how we tidd of two arguments here, and S1.library should look familiar now, and Lnodes refers to a "time varying covariate." For now we're going to leave this as a NULL, but we'll see how to use it soon.

```
rexpit <- function(x) rbinom(n=length(x), size=1, prob=plogis(x))

Email: tutorcs@163.com

n <- 1000

W1 <- rnorm(n)

W2 <- rbinom(n, size=1, prob=0.3)
W3 <- rnorm(n)

A <- rexpit(-1 + 2 * W1 + W3)

Y <- rexpit(-0.5 + 2 * W1^2 + 0.5 * W2 - 0.5 * A + 0.2 * W3 * A - 1.1 * W3)

data <- data.frame(W1, W2, W3, A, Y)

result <- ltmle(data, those with the content of the
```

#### Longitudinal Data Structure

Now imagine we instead of a time ordering like this:

$$W- > A1- > L- > A2- > Y$$

We can simulate some more data to reflect this structure, and then fit a ltme() function. Notice how now we have "L" nodes. In the data structure specified above, we have some baseline covariates that occur before the first treatment, some time dependent covariate that comes after the first treatment but before the second, then a second treatment and then outcome. Notice how we can now add L nodes that occur in between the two treatments so that we can deal with this "time-dependent confounding".

```
n <- 1000
W <- rnorm(n)
A1 <- rexpit(W)
L <- 0.3 * W + 0.2 * A1 + rnorm(n)
A2 <- rexpit(W + A1 + L)</pre>
```

# Y <- rexpit(W - 0.6 \*程, 序程等 代做 CS编程辅导 data <- data.frame(W程, 序程等 )

ltmle(data, Anodes=c("A1", "A2"), Lnodes="L", Ynodes="Y", abar=c(1, 1), SL.library = sl\_libs)

```
x, y, weights, offset, alpha, nobs,
## Error in lognet()

## TMLE Estimate:
```

The ltmle vignette provides even more examples, including for censored data. The main concept here is that 1tmle allows for causal estimates in observational data in complicated treatment regimes such as staggered adoption, subject dropo to implicate eathers to res (#163.com

#### Concluding Thoughts

We have covered a lot of group this year! To recons: 9476

- Reproducible Data Science
  - GitHub/version control
- Collaborative datasMachine Learning //tutorcs.com
- - Supervised Learning
    - \* Regression
    - \* Classification
  - Unsupervised Learning
    - \* Dimensionality Reduction
    - \* Clustering/grouping
- Text Analysis
  - Text preprocessing
  - Dictionary methods, word2vec, sentiment analysis
  - Prediction
- Causal Inference
  - Matching
  - Regression Discontinuity
  - Diff-in-Diffs/Synthetic Control
  - Sensitivity Analysis
  - SuperLearner/Targeted Maximum Likelihood Estimation

This covers a lot of computational social science! But there's still more. As you're thinking about where to go next, I recommend exploring these areas:

- · Computational Tools/Data Acquisition Web scraping 程序代写代做 CS编程辅导

  - Bash/CLI
  - XML/HTML parsing (BeautifulSoup)
- High Performance ed "embarrassingly parallel" techniques, but there are other Parallel proc more advance
  - Amazon Weł soft Azure cloud computing
  - Secure File 7
- Deep Learning
  - We covered s nore applications would be good
  - GPU acceler
  - - Deep Learning
- Machine Learning and Causal Inference
  - Meta-estimators (like TMLE)
  - Heterogeneou Weath Fffects: cstutorcs

## Appendix for SL & LTMLE

a) We can now plot Sur Assignment Project Exam Help

```
roc_df <- roc_curve(a)idation,7493
          truth = as.factor(obs))
roc_df %>%
  ggplot() +
  geom_point(aes(x = specficity, y = 1))
  geom\_line(aes(x = specificity, y = 1 - sensitivity)) +
  theme_fivethirtyeight() +
  theme(axis.title = element_text()) +
  ggtitle('AUC-ROC Curve for SuperLearner') +
  xlab('Specificity') +
  ylab('Sensitivity')
```
